PARENT-CASE:

CROSS REFERENCE TO RELATED APPLICATION This application is a

Continuation-In-Part of U.S. patent application Ser. No. 08/380,755 filed

Jan. 31, 1995 which is a Continuation-In-Part of U.S. patent application Ser.

No. 08/250,791 filed May 27, 1994, the disclosures of both of which are incorporated herein entirely by reference.

TTL:

Downloading operating system software through a broadcast channel

BSPR:

An operating system includes programming to control internal operations of the control processor, such as those necessary to execute specific types of communications over the network, graphics drivers, etc. The operating system typically allows the set-top to run a variety of downloaded applications programs, preferably made available by a number of service providers. It is desirable to periodically update the operating system software, as improvements are developed, without having a technician manually service each terminal. The downloading of an operating system program for running the terminal device

raises a more complicated set of problems relating to who can download such software to which types of terminals.

BSPR:

Access to the ability to modify the operating system must be carefully controlled. If access were open, an unscrupulous party could write a destructive operating system, e.g. that would allow the terminal to access only one provider's services or that might cause the terminal to begin upstream transmissions in some manner which would disrupt upstream transmissions of other terminals. The downloaded operating system would need to correspond to the particular type of set-top terminal to insure compatibility. Also, the downloading of the operating system must be particularly error free to insure that errant reception and overwriting of operation system software does not in some corrupt or disable terminal operation.

BSPR:

A need therefore still exists to reliably and securely download operating system software to the digital set-top terminal through a widely accessible broadcast channel.

BSPR:

The present invention addresses the above noted needs by providing methods, systems and terminal device structures for downloading operating system software to programmable set-top terminal devices through digital broadcast channels.

DEPR:

With the present invention the set-top terminal 100

(preferably the DET portion 102 thereof) receives and stores downloaded operating system software and application software. The terminal 100 can establish a point to point link to interactive equipment operated by a video information provider (VIP) and receive interactive applications software through the point to point link, as disclosed in the above incorporated 08/250,791 application. The key features of the present invention, however, relate to downloading an operating system through a broadcast channel, therefore the following description concentrates on a broadcast type network implementation and downloading of the operating system through a broadcast channel.

DEPR:

A party providing the operating system upgrade service operates a data carousel application. With this type of application, a digital data stream cyclically repeats, and in accord with the present invention, the network carries the repeating data stream on a broadcast channel. The data stream may include video, audio, data and executable code. For an operating system download, the repeating data consists of a data file containing new operating system code.

DEPR:

The DET 102 processes the MPEG II packets in the resultant stream based on their respective PID values. Packets having PID values assigned to audio or video are processed by corresponding decoders and associated driver circuits to produce signals for driving the television set 103 to display the program

information to the user. Downloaded software, however, is transferred as private data to the microprocessor of the DET. Of particular note for purposes of the present invention, if the software relates to an operating system, the microprocessor executes the upgrade routine to replace the existing operating system stored in non-volatile RAM with the newly received operating system software.

DEPR:

The network interface module 101 takes the form of a plug in module. In one embodiment, the module 101 would be similar to a daughter board or option card which can be plugged into a back plane of a personal computer (PC). In such an embodiment, typically a technician could replace the module in either the field or the shop, to modify a set-top device 100 to connect to and communicate over a different network, and the technician would modify associated communications control software in the system memory. Alternative implementations may use a user replaceable cartridge type network interface module, similar to a video game cartridge, which may include memory in the module for storage of the communications control. As a further alternative, the network interface module could include a digital signal processor controlled by the CPU of the DET 102 and input/output connections compatible with all of the digital broadband networks currently available. The downloaded operating system software stored in the system memory of the DET would control operations of the digital signal processor to send and receive signals in accord with the particular network to

which the subscriber chooses to connect the set-top device 100.

DEPR:

The DET 102 includes a CPU 105, comprising a 386, 486 PENTIUM.TM., or Motorola 6800 Series microprocessor 110 and associated system memory 120. The system memory 120 includes at least 2 mbytes of volatile dynamic random access memory (RAM) 122 and 1 mbyte of non-volatile random access memory (NVRAM) 121. In the preferred embodiment, the NVRAM 121 is a flash memory device. The CPU 105 also includes a read only memory (ROM) 115, either as a separate element connected to the microprocessor 110 as shown or as an element within the microprocessor 110. The ROM 115 stores "loader" programming needed to control wake-up. The non-volatile RAM 121 stores the operating system for the microprocessor 110. In operation, the volatile RAM 122 temporarily stores applications programs for execution by the microprocessor 110 as well as related data files, and during operating system download operations, the RAM 122 temporarily stores the new operating system.

DEPR:

In the preferred embodiment, the operating system for the DET 102 includes a version of a PC type operating system, e.g. OS-9. In addition, the operating system for the DET 102 includes the various drivers necessary for the DET microprocessor 110 to operate the associated peripherals, e.g. the Digital Audio/Video Processor 125, the Personal Computer Memory Card Industry Association (PCMCIA) port 155, the RS-232 transceiver

151, etc. The set-top operating system also includes the resident cable television emulation software, i.e. as needed to facilitate reception of broadcast programs through the particular network. This operating system is stored in a portion of the non-volatile RAM 121 having a relatively low level of protection. When a new operating system is installed, as discussed more fully below, the new operating system replaces the entire operating system previously stored in the non-volatile RAM. The level of protection here provided enables rewriting the operating system using a broadcast channel download procedure, however, there is sufficient protection to limit storage to only acceptable software from an authorized provider.
